Prioritizing what to work on: Spam classification example

#### **Building a spam classifier**

From: cheapsales@buystufffromme.com

To: ang@cs.stanford.edu

Subject: Buy now!

Deal of the week! Buy now!
Rolex w4tchs - \$100
Med1cine (any kind) - \$50
Also low cost M0rgages
available.

Span (1)

From: Alfred Ng

To: ang@cs.stanford.edu Subject: Christmas dates?

Hey Andrew,
Was talking to Mom about plans
for Xmas. When do you get off
work. Meet Dec 22?
Alf

Non-spom (0)

#### **Building a spam classifier**

Supervised learning. x =features of email. y =spam (1) or not spam (0).

Supervised learning. 
$$x = \text{features of email. } y = \text{spam (1) or not spam (0)}.$$

Features  $x$ : Choose 100 words indicative of spam/not spam.

Leg. deal, buy, discont, andrew, now, ...

Significant in end of the week! Buy now!

Deal of the week! Buy now!

Note: In practice, take most frequently occurring n words (10,000 to 50,000) in training set, rather than manually pick 100 words.

#### **Building a spam classifier**

How to spend your time to make it have low error?

- Collect lots of data
  - E.g. "honeypot" project.
- Develop sophisticated features based on email routing information (from email header).
- Develop sophisticated features for message body, e.g. should "discount" and "discounts" be treated as the same word? How about "deal" and "Dealer"? Features about punctuation?
- Develop sophisticated algorithm to detect misspellings (e.g. m0rtgage, med1cine, w4tches.)

Machine Learning

## Machine learning system design

### Error analysis

#### **Recommended approach**

- Start with a simple algorithm that you can implement quickly. Implement it and test it on your cross-validation data.
- Plot learning curves to decide if more data, more features, etc. are likely to help.
- Error analysis: Manually examine the examples (in cross validation set) that your algorithm made errors on. See if you spot any systematic trend in what type of examples it is making errors on.

#### **Error Analysis**

 $m_{CV} =$  500 examples in cross validation set Algorithm misclassifies 100 emails.

Manually examine the 100 errors, and categorize them based on:

- -> (i) What type of email it is phorma, replica, steal passwards,
- (ii) What cues (features) you think would have helped the algorithm classify them correctly.
- Pharma: 12
- Replica/fake: 4
- → Steal passwords: 53
  - Other: 31

- Deliberate misspellings: 5
  - (m0rgage, med1cine, etc.)
  - Unusual email routing: 16
- → Unusual (spamming) punctuation: 32

The importance of numerical evaluation

Ability to produce a numerical evaluation of the algorithm based on a single real number. Key when developing algorithms & trying new ideas/

Should discount/discounts/discounted/discounting be treated as the same word?

Can use "stemming" software (E.g. "Porter stemmer") universe/university.

Error analysis may not be helpful for deciding if this is likely to improve performance. Only solution is to try it and see if it works.

Need numerical evaluation (e.g., cross validation error) of algorithm's performance with and without stemming.

Without stemming: 54, error With stemming: 3-/ error

Distinguish upper vs. lower case (Mom/mom): 3.7.

Machine Learning

Error metrics for skewed classes

#### **Cancer classification example**

Train logistic regression model  $h_{\theta}(x)$  .  $\underline{y=1}$  if cancer,  $\underline{y=0}$  otherwise)

Find that you got 1% error on test set.

(99% correct diagnoses)

Only 0.50% of patients have cancer.

```
function y = \text{predictCancer}(x)

\Rightarrow y = 0; %ignore x!

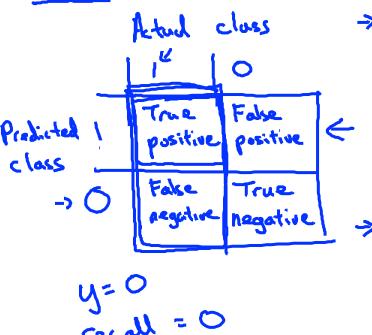

return

\Rightarrow qq 2d, any (0.8% error)

\Rightarrow qq .5d, any (0.5% error)
```

#### **Precision/Recall**

y = 1 in presence of rare class that we want to detect

#### Precision

(Of all patients where we predicted y=1, what fraction actually has cancer?)

True positives True positive

True positive

True positive

True positive

#### Recall

(Of all patients that actually have cancer, what fraction did we correctly detect as having cancer?)

True positives True positives

True positives

True positives

Machine Learning

Trading off precision and recall

#### **Trading off precision and recall**

- Predict 0 if  $h_{\theta}(x) < 0.5$   $f_{\theta}(x) \leq 1$  Predict 0 if  $h_{\theta}(x) < 0.5$   $f_{\theta}(x) < 0.5$
- $\rightarrow$  Suppose we want to predict y=1 (cancer) only if very confident.

→ Suppose we want to avoid missing too many cases of cancer (avoid false negatives).

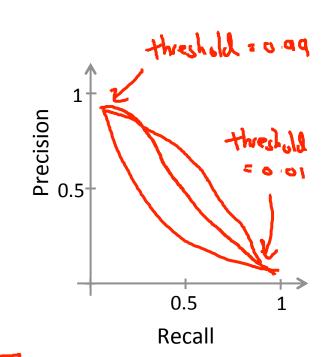

precision = true positives

no. of predicted positive

true positives

true positives

no. of actual positive

More generally: Predict 1 if  $h_{\theta}(x) \geq \text{ threshold}$ 

### F<sub>1</sub> Score (F score)

How to compare precision/recall numbers?

	Precision(P)	Recall (R)	\ /	
Algorithm 1	0.5	0.4		<b>(</b>
Algorithm 2	0.7	0.1	X	<b>~</b>
Algorithm 3	0.02	1.0		<b>~</b>
Average: $\frac{P+R}{2}$			Predict y=1 a	Il the time
F <sub>1</sub> Score:	$2\frac{PR}{P+R}$	P=0 00 P=1 and	R=0 ⇒	F-sum = 1 -

Machine Learning

# Data for machine learning

#### Designing a high accuracy learning system

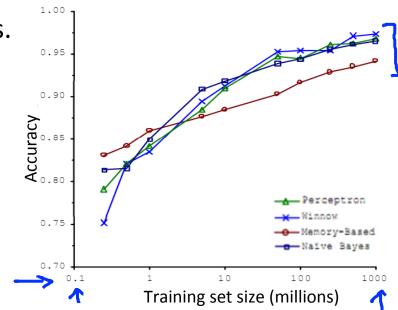

E.g. Classify between confusable words.

{to, two, too}, {then, than}

For breakfast I ate <u>two</u> eggs.

#### Algorithms

- -> Perceptron (Logistic regression)
- -> Winnow
- -> Memory-based
- → Naïve Bayes

"It's not who has the best algorithm that wins.

It's who has the most data."

Its true most of the time...

#### Large data rationale

When does lots of data help?

Assume feature  $x \in \mathbb{R}^{n+1}$  has sufficient information to predict y accurately.

Example: For breakfast I ate eggs. Counterexample: Predict housing price from only size (feet<sup>2</sup>) and no other features.

Useful test: Given the input x, can a human expert confidently predict y?

#### Large data rationale

Use a learning algorithm with many parameters (e.g. logistic regression/linear regression with many features; neural network with many hidden units).

low varione

Use a very large training set (unlikely to overfit)
